Seesaw Principle — Idea

Theorem (Weil)

A limit of trivial line bundles on a complete variety is again trivial.

Seesaw Principle — Idea

Theorem (Weil)

A limit of trivial line bundles on a complete variety is again trivial.

$\downarrow$ making this idea more precise

Theorem (Statement for varieties over $k = \bar{k}$)

V complete, T any ("parameter space"), $\mathcal{L} \in \mathrm{Pic}(V \times T)$. Then

$$Z := \{ t \in T \mid \mathcal{L}_t \text{ is trivial} \} \lhook\joinrel\not\longrightarrow T$$

is closed and $\mathcal{L}|_{V \times Z}$ is the pullback of a line bundle on Z.

Seesaw Principle — Idea

Theorem (Weil)

A limit of trivial line bundles on a complete variety is again trivial.

$\downarrow$ making this idea more precise

Theorem (Statement for varieties over $k = \bar{k}$)

V complete, T any ("parameter space"), $\mathcal{L} \in \mathrm{Pic}(V \times T)$. Then

$$Z := \{t \in T \mid \mathcal{L}_t \text{ is trivial} \} \longleftrightarrow T$$

is closed and $\mathcal{L}|_{V \times Z}$ is the pullback of a line bundle on Z.

This is the conclusion of the subsection on the seesaw principle in [Mil08], which can be read independently. This statement will be used to **reduce** the Theorem of the Cube to an easier case.

Seesaw Principle — Generalisation

Theorem ([Bha17, Theorem 6.3] or [Fra18, Theorem 5])

Let $f : X \to S$ be a proper flat morphism of (locally) noetherian schemes with geometrically integral fibres and let $\mathcal{L} \in X$. Then

$$Z := \{ s \in S \mid \mathcal{L}_s \text{ is trivial} \} \lhook\joinrel\not\longrightarrow S$$

and $\mathcal{L}|_{f^{-1}(Z_{\mathrm{red}})} = f^*\mathcal{M}_0$ for some $\mathcal{M}_0 \in \mathrm{Pic}(Z_{\mathrm{red}})$. Moreover, there exists a (unique) closed subscheme structure on Z such that $\mathcal{L}|_{f^{-1}(Z)} = f^*\mathcal{M}$ for some $\mathcal{M} \in \mathrm{Pic}(Z)$ and Z is universal amongst all (locally) noetherian S-schemes with this property.

Seesaw Principle — Generalisation

Theorem ([Bha17, Theorem 6.3] or [Fra18, Theorem 5])

Let $f: X \to S$ be a proper flat morphism of (locally) noetherian schemes with geometrically integral fibres and let $\mathcal{L} \in X$. Then

$$Z := \{ s \in S \mid \mathcal{L}_s \text{ is trivial} \} \hookrightarrow\!\!\!\!\!\!\!\not\;\;\; \longrightarrow S$$

and $\mathcal{L}|_{f^{-1}(Z_{\mathrm{red}})} = f^*\mathcal{M}_0$ for some $\mathcal{M}_0 \in \mathrm{Pic}(Z_{\mathrm{red}})$. Moreover, there exists a (unique) closed subscheme structure on Z such that $\mathcal{L}|_{f^{-1}(Z)} = f^*\mathcal{M}$ for some $\mathcal{M} \in \mathrm{Pic}(Z)$ and Z is universal amongst all (locally) noetherian S-schemes with this property.

Brian Conrad proves this using existence and separatedness of $\mathrm{Pic}_{X/S}$ [Con15, Theorem 3.1.1]: $\mathscr{O}_X$ gives us $[\mathscr{O}_X]: S \to \mathrm{Pic}_{X/S}$, whose image we identify with S, and then $Z = [\mathcal{L}](S) \cap [\mathscr{O}_X](S)$. Conversely, assuming $\mathrm{Pic}_{X/S}$ exists, the seesaw theorem implies that it is separated [Fra18, Remark 2.4.2] (automatic if $S = k$).

Seesaw Principle — Particular case in a picture

$$
\begin{tikzcd}
X & & Y \\
& X \times Y \arrow[ul] \arrow[ur, dashed] \arrow[dl, dashed] \arrow[dr] & \\
X & & Y
\end{tikzcd}
$$

Seesaw Principle — Particular case in a picture

$$
\begin{tikzcd}
X & & Y \\
& X \times Y \arrow[ul] \arrow[ur, dashed] \arrow[dl, dashed] \arrow[dr] & \\
X & & Y
\end{tikzcd}
$$

We have some $\mathcal{L} \in \mathrm{Pic}(X \times Y)$. We can think of $\mathcal{L}$ as a weight distribution on the two extremes X and Y of this seesaw: the more points $x \in X$ such that $\mathcal{L}|_{\{x\}\times Y}$ is trivial, the heavier $\mathcal{L}$ sits on X.

Seesaw Principle — Particular case in a picture

$$\begin{tikzcd}
X & & Y \\
& X \times Y \arrow[ul] \arrow[ur, dashed] \arrow[dl, dashed] \arrow[dr] & \\
X & & Y
\end{tikzcd}$$

We have some $\mathcal{L} \in \mathrm{Pic}(X \times Y)$. We can think of $\mathcal{L}$ as a weight distribution on the two extremes X and Y of this seesaw: the more points $x \in X$ such that $\mathcal{L}|_{\{x\} \times Y}$ is trivial, the heavier $\mathcal{L}$ sits on X. In this case, let's say, we have $\mathcal{L}|_{X \times \{y\}}$ trivial for all $y \in Y$. Then $\mathcal{L}$ sits with full weight on Y, so the seesaw principle tells us that there must be some line bundle on Y from which $\mathcal{L}$ is the pullback.

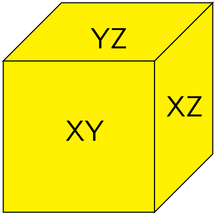
Theorem of the Cube — Statement

Theorem (Statement for varieties over $k = \bar{k}$)

X, Y, Z complete and $\mathcal{L} \in \mathrm{Pic}(X \times Y \times Z)$ such that

$$\mathcal{L}|_{X \times Y \times \{z_0\}}, \mathcal{L}|_{X \times \{y_0\} \times Z} \text{ and } \mathcal{L}|_{\{x_0\} \times Y \times Z}$$

are trivial. Then $\mathcal{L}$ is trivial.



If the restriction of $\mathcal{L} \in \mathrm{Pic}(\mathrm{Cube})$ to each face XY, YZ and XZ is trivial, then $\mathcal{L}$ is trivial.

Theorem of the Cube — Generalisation
